DEVOPS FUNDAMENTALS MINI PROJECT REPORT

Cloud-Based Linux Server Deployment with GitHub Version Control and Automation

Student: Khushi Mishra

Batch Code: 530

Platform: AWS EC2, Ubuntu Linux, Apache2, Git/GitHub

Project Date: 18 October 2026

Prepared using project details and screenshots supplied by the student.

1. Project Overview

This project demonstrates foundational DevOps practices by deploying a website on an AWS EC2 Ubuntu server, managing files with Git and GitHub, automating administration tasks with Bash scripts, creating timestamped website backups, and reviewing system and authentication logs.

2. Objectives

• Provision and access a Linux server in AWS.
• Install and manage the Apache2 web service.
• Publish a website using the server's public address.
• Use Git/GitHub for version control and remote storage.
• Automate health checks, service monitoring, and website backups.
• Generate a log report containing authentication activity, system errors, and warnings.

3. AWS Architecture

Developer / Git client → GitHub repository → AWS EC2 Ubuntu instance → Apache2 → Website

The EC2 security group controls inbound network access. SSH is used for remote administration, while HTTP traffic reaches Apache on port 80. For safer operation, restrict SSH access to trusted source IP addresses rather than opening it to everyone.

4. Implementation Steps

1. Launch an Ubuntu EC2 instance and connect over SSH.
2. Update package metadata and install Apache2 and required command-line tools.
3. Place the website file at the Apache document root.
4. Create Bash scripts for health checks, Apache monitoring, and website backup.
5. Generate a log report from the server's available logs.
6. Track project files with Git, commit changes, and push them to GitHub.
7. Capture screenshots as evidence of setup and script output.

5. Automation Scripts

server-health.sh: reports information such as CPU, memory, disk usage, running processes, and uptime.
apache-monitor.sh: checks Apache2 service status and is intended to restart it if stopped.
website-backup.sh: creates a timestamped compressed website backup in the Backup directory.
generate-log-report.sh: collects available log information into log-report.txt, including failed login attempts, SSH activity, system errors, and warnings.

6. Git and GitHub

Git was used to track project changes, create commits, and push the main branch to the remote GitHub repository. The latest reported push completed successfully.
Repository: https://github.com/khushiiii05/DevOps-Project

7. Challenges Faced

• Learning Linux commands, file permissions, and service management.
• Editing and organizing project files on the server.
• Configuring Git authentication and pushing changes to GitHub.
• Understanding authentication and system logs.
• Creating repeatable backups with timestamps.

8. Learning Outcomes

The project provided practical experience with Linux administration, AWS EC2, Apache2, Bash scripting, log inspection, compressed backups, and Git/GitHub version control. It also reinforced the importance of checking service status and securing remote access.

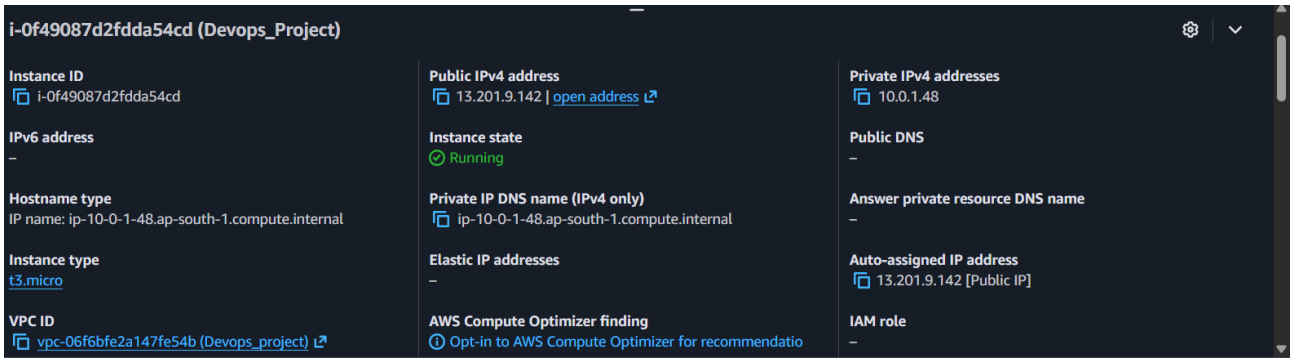

9. Conclusion

This mini project combines core introductory DevOps tasks in a small cloud-hosted environment. Future improvements could include scheduled backups, alerting, stricter security group rules, and automated deployment.

Appendix A. Project Screenshots

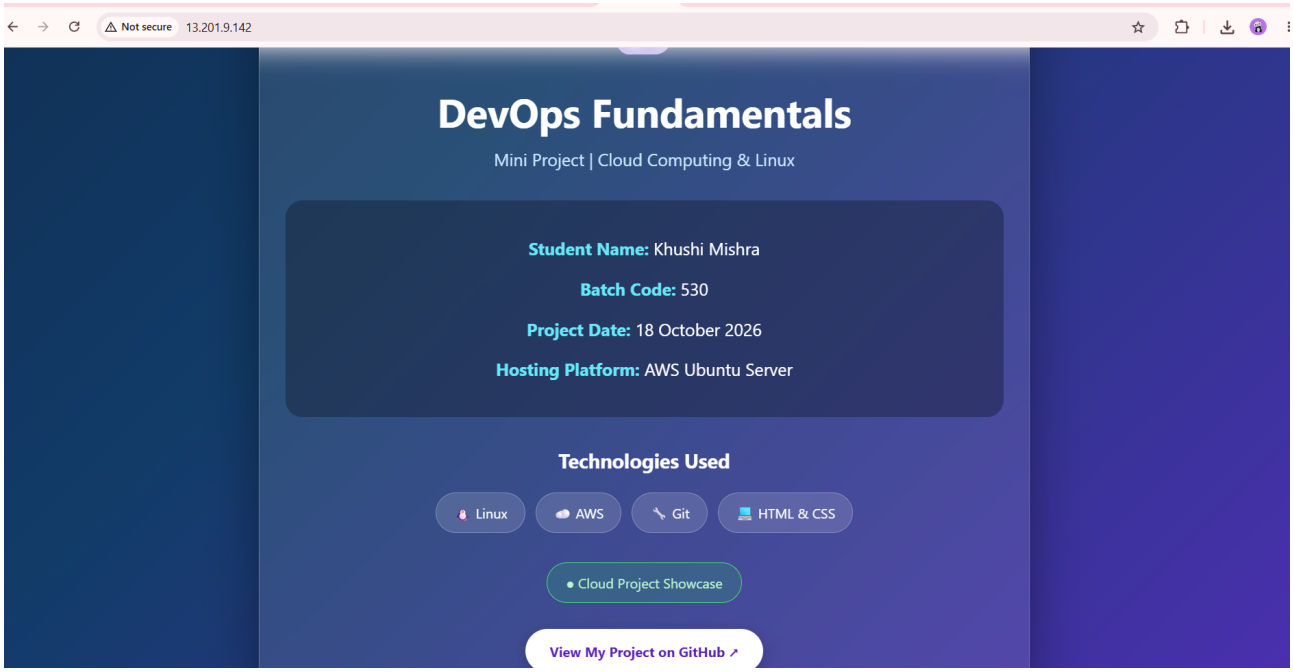

Screenshots supplied by the student are included below as evidence of setup and testing.
